Charmless two-body decays at Belle and prospects at Belle II

Bilas Pal

(On behalf of the Belle Collaboration)

Charmless hadronic $B$ decays are a good testing ground for the Standard Model (SM) of Particle Physics. The dominant amplitudes are CKM suppressed tree diagrams and/or $b \rightarrow s$ or $b \rightarrow d$ loop ("penguin") diagrams. Non-SM particle could appear in the loop, and hence these decays are sensitive to search for New Physics (NP). Some of the recent measurements of two-body charmless hadronic $B$ decays from Belle and their prospects at Belle II are discussed.

INTRODUCTION

Charmless hadronic final states in $B$ decays have branching fractions of order $10^{-5}$ or less, since either the final state is reached by the $b \rightarrow u$ transition, which is suppressed by the small CKM matrix element $|V_{ub}|$, or the transition is loop-suppressed. Charmless decays are a good place to observe direct $CP$ violation, since the smallness of the leading amplitude often implies that another amplitude with a different CKM factor is of similar size. If the two amplitudes also have a substantial (strong) phase difference, this leads to size-able direct $CP$ violation. This is often implied that another amplitudes is a factor of 5 larger than that used previously. Improved tracking, photon reconstruction, and continuum suppression algorithms are also used in this analysis.

We find the evidence of the decay $B^0 \rightarrow \eta \pi^0$ [12], where the candidate $\eta$ mesons are reconstructed via $\eta \rightarrow \gamma \gamma$ ($\eta_{\gamma \gamma}$) and $\eta \rightarrow \pi^+ \pi^- \pi^0$ ($\eta_{\pi \pi}$) decays and $\pi^0$ via $\pi^0 \rightarrow \gamma \gamma$. Results of the fit to the variables, beam-energy-constrained mass $M_{bc} = \sqrt{E_{beam}^2 - (p_0)^2 c^2}/c^2$, energy difference $\Delta E = E_B - E_{beam}$ and continuum suppression variable $C_{NB} = \ln(C_{NB}/C_{MIN})$, are given in Table I. The combined branching fraction is determined by simultaneously fitting both $B^0 \rightarrow \eta_{\gamma \gamma} \pi^0$ and $B^0 \rightarrow \eta_{\pi \pi} \pi^0$ samples for a common $B$ branching fraction $B$ for the decay $B^0 \rightarrow \eta \pi^0$. The errors listed are statistical only. The significance includes both statistical and systematic uncertainties.

EVIDENCE FOR THE DECAY $B^0 \rightarrow \eta \pi^0$

The decay $B^0 \rightarrow \eta \pi^0$ proceeds mainly via a $b \rightarrow u$ Cabibbo- and color-suppressed "tree" diagram, and via a $b \rightarrow d$ "penguin" diagram, as shown in Fig. 1. The branching fraction of this decay mode can be used to constrain isospin-breaking effects on the value of $\sin 2\theta_2 (\sin 2\alpha)$ measured in $B \rightarrow \pi \pi$ decays [1] [2]. It can also be used to constrain $CP$-violating parameters ($C_{\eta K}$ and $S_{\eta K}$) governing the time dependence of $B^0 \rightarrow \eta K^0$ decays [3]. The branching fraction is estimated using QCD factorization [4], soft collinear effective field theory [5], and flavor SU(3) symmetry [6] and is found to be in the range $(2 - 12) \times 10^{-7}$.

![Diagram](a) Tree and (b) penguin diagram contributions to $B \rightarrow \eta \pi^0$.

Several experiments [7-11], including Belle, have searched for this decay mode. The most stringent limit on the branching fraction is $B(B \rightarrow \eta \pi^0) < 1.5 \times 10^{-6}$ at 90% confidence level (C.L.), given by BaBar experiment [11]. The analysis presented here uses the full data set of the Belle experiment running on the $T(4S)$ resonance at the KEKB asymmetric-energy $e^+e^-$ collider. This data set corresponds to $753 \times 10^6 BB$ pairs, which is a factor of 5 larger than that used previously.

![Diagram](a) Tree and (b) penguin diagram contributions to $B \rightarrow \eta \pi^0$.

The branching fraction for $B^0 \rightarrow \eta \pi^0$ is estimated using statistical and systematic uncertainties. The significance includes both statistical and systematic uncertainties. The results are $B(B^0 \rightarrow \eta \pi^0) = (4.1^{+1.7}_{-1.5} \pm 0.5) \times 10^{-7}$ when the first uncertainty is statistical and the second is systematic.
The branching fraction of $B^0 \to \eta \eta$ is obtained by a simultaneous fit to the $\eta \gamma \gamma$, $\eta \pi^+ \pi^- \pi^0$ and $\eta_3 \pi_3$ decay channels. We perform a three dimensional extended unbinned maximum likelihood fit to the variables $M_{bc}$, $\Delta E$ and $C_{NB}'$, as shown in Fig. 2. We extract $23.6^{+8.1}_{-6.9}$, $9.2^{+3.2}_{-2.7}$ and $2.7^{+0.9}_{-0.8}$ signal events from the $\eta \gamma \gamma$, $\eta \pi^0 \pi^0$ and $\eta_3 \pi_3$ decay channels, respectively. The measured branching fraction is

$$B(B^0 \to \eta \eta) = (5.9^{+2.1}_{-1.8} \pm 1.4) \times 10^{-7},$$

where the first uncertainty is statistical and the second is systematic. The significance of the result is 3.3 standard deviations, and provides the first evidence of this decay.

FIG. 2. Signal enhanced projections of the simultaneous fit for the decay $B^0 \to \eta \pi^0$: (a), (b) $M_{bc}$; (c), (d) $\Delta E$; (e), (f) $C_{NB}'$. The top (bottom) row corresponds to $\eta \to \gamma \gamma$ ($\eta \to \pi^+ \pi^- \pi^0$) decays. Points with error bars are data; the (green) dashed, (red) dotted and (magenta) dot-dashed curves represent the signal, continuum and charmless rare backgrounds, respectively, and the (blue) solid curves represent the total PDF.

FIG. 3. Signal-enhanced fit projections for the (top) $B^0 \to \eta_3 \pi_3$ (moddle) $B^0 \to \eta_3 \pi_3$ and (bottom) $B^0 \to \eta_3 \pi_3$ fit results. The points with the error bars show the data; the (black) solid lines show the total PDF; the (red) dashed lines show the signal; the (blue) dotted lines show the continuum background; and the (green) dot-dashed lines show the other $B \bar{B}$ background.

EVIDENCE FOR THE DECAY $B^0 \to \eta \eta$

This decay is similar to the decay discussed in the previous section. Previously this decay mode is studied by the Belle, BaBar, CLEO and L3 experiments [13] and the most stringent limit on the branching fraction $B(B \to \eta \eta) < 1.0 \times 10^{-6}$ at 90% C.L. is set by the BaBar experiment [14]. Here we update the previous Belle result by using the full data set of the Belle experiment running on the $T(4S)$ [15].

BRANCHING FRACTION AND CP ASYMMETRY OF $B^0 \to \pi^0 \pi^0$

The decay $B^0 \to \pi^0 \pi^0$ is an important input for the isospin analysis in the $B \to \pi \pi$ system [16]. Among the $B \to \pi \pi$ decays, this decay is least well determined [13]. This decay is also important to probe the disagreement between quantum-chromodynamics-based factorization, which predicts the branching fraction below $1 \times 10^{-6}$ [17], and previous measurements [13] from Belle and BaBar. Here, we present new measurements of $B^0 \to \pi^0 \pi^0$ based on a 693 fb$^{-1}$ data sample that contains 752 $\times 10^6$ $B \bar{B}$ pairs [18].
We reconstruct $B^0 \rightarrow \pi^0\pi^0$ candidates from the subsequent decay of $\pi^0$ mesons to two photons. In addition to photons reconstructed from electromagnetic calorimeter clusters, which do not match any charged track in the central drift chamber, photons that convert to $e^+e^-$ pairs in the silicon vertex detector are recovered and reconstructed as $\pi^0 \rightarrow e^+e^-\gamma$. This provides a 5.3% increase in detection efficiency. The dominant background arises from the continuum process.

To suppress this background, which tend to be jet-like from spherical $B\bar{B}$ events, a Fisher discriminant ($T_c$) is constructed using the so-called event shape variables.

The signal yield and the direct CP asymmetry ($A_{CP}$) are extracted via an unbinned extended maximum likelihood fit to the variables $M_{bc}$, $\Delta E$ and $T_c$ in bins of flavor tagging variable.

![FIG. 4. Projections of the fit results onto (left) $\Delta E$, (middle) $M_{bc}$, (right) $T_c$ are shown in the signal enhanced region: 5.275 GeV$/c^2 < M_{bc} < 5.285$ GeV$/c^2$, $-0.15 < \Delta E < 0.05$ GeV, and $T_c > 0.7$. Each panel shows the distribution enhanced in the other two variables. Data are points with error bars, and fit results are shown by the solid black curves. Contributions from signal, continuum $\phi_2$, combined $\rho\tau$ and other rare $B$ decays are shown by the dashed (blue), dotted (green), and dash-dotted (red) curves, respectively. The top (bottom) row panels are for events with positive (negative) flavor tagging variable.](image)

Figure 4 shows the signal-enhanced projections of the fits to data in $M_{bc}$, $\Delta E$ and $T_c$. We obtain a signal yield of $217 \pm 32$ events. The branching fraction and $A_{CP}$ are determined to be

$$B(B^0 \rightarrow \pi^0\pi^0) = (1.31 \pm 0.19 \pm 0.19) \times 10^{-6},$$

$$A_{CP} = +0.14 \pm 0.36 \pm 0.10,$$

where the quoted uncertainties are statistical and systematic, respectively. Combining our results for $B^0 \rightarrow \pi^0\pi^0$ with the previous Belle measurements for $B^0 \rightarrow \pi^+\pi^-\pi^-\pi^+$ allows us to employ an isospin analysis of Ref. 10 to constrain the CKM angle $\phi_2$. Our results exclude $15.5^\circ < \phi_2 < 75.0^\circ$ at 95% confidence level. The measured branching fraction is smaller than our previously published result [13] though consistent within uncertainties. The difference could be due to a substantially smaller fraction of data for which ECL timing information was available (113 of 253 fb$^{-1}$) in the earlier measurement and the subsequent extrapolation to the full data set. The results reported here supersede our earlier published values and agrees with BaBar measurement [13] within combined uncertainties. While this result is closer to theory predictions than the earlier Belle and BaBar measurements, it is still larger than expectations based on the factorization model [19]. It is in agreement with the recent works of Qiao et al. [20] as well as Li and Yu [21] which employ different theoretical approaches. The upcoming Belle II experiment [22], with its projected factor of 50 increase in luminosity, will enable precision measurements of $B$ and CP asymmetry of $B^0 \rightarrow \pi^0\pi^0$ and other $B \rightarrow \pi\pi$ decays to strongly constrain $\phi_2$.

**OBSERVATION OF THE DECAY $B^0_s \rightarrow K^0\bar{K}^0$**

The two-body decays $B^0_s \rightarrow h^+h^-$, where $h^0$ is either a pion or kaon, have now all been observed [13]. In contrast, the neutral-daughter decays $B^0_s \rightarrow h^0h^0$ have yet to be observed. The decay $B^0_s \rightarrow K^0\bar{K}^0$ is of particular interest because the branching fraction is predicted to be relatively large. In the SM, the decay proceeds mainly via a $b \rightarrow s$ transition as shown in Fig. 5 and the branching fraction is predicted to be in the range $(16 - 27) \times 10^{-6}$ [23]. The presence of non-SM particles or couplings could enhance this value [24]. It has been pointed out that CP asymmetries in $B^0_s \rightarrow K^0\bar{K}^0$ decays are promising observables in which to search for new physics [24].

![FIG. 5. Loop diagram for $B^0_s \rightarrow K^0\bar{K}^0$ decays.](image)
latter two channels dominate, with production fractions of $f_{B_s^0 \bar{B}_s^0} = (7.3 \pm 1.4)\%$ and $f_{B_s^0 \bar{B}_s^0} = (87.0 \pm 1.7)\%$ [23]. The $B_s^0$ decays via $B_s^0 \to B_s^0 \gamma$, and the $\gamma$ is not reconstructed.

Candidate $K^0$ mesons are reconstructed via the decay $K_S^0 \rightarrow \pi^+ \pi^-$ and require that the $\pi^+ \pi^-$ invariant mass be within 12 MeV/$c^2$ of the nominal $K_S^0$ mass [13].

In order to extract the signal yield, we perform a three-dimensional (3D) unbinned maximum likelihood fit to the variables, $M_{\text{had}}$, $\Delta E$, and continuum suppression variable $C'_{NN} = \ln \left( \frac{C_{\text{NN}} - C_{\text{min}}}{C_{\text{NN}} - C_{\text{max}}} \right)$. We extract $29.0^{+8.5}_{-7.6}$ signal events and 1095.0^{+33.9}_{-33.4} continuum background events. Projections of the fit are shown in Fig. 6. The branching fraction of the decay $B_s^0 \to K^0 \bar{K}^0$ is measured to be $29.0^{+8.5}_{-7.6} \times 10^{-6}$.

$$B(B_s^0 \to K^0 \bar{K}^0) = (19.6^{+5.8}_{-5.1} \pm 1.0 \pm 2.0) \times 10^{-6},$$ (1)

where the first uncertainty is statistical, the second is systematic, and the third reflects the uncertainty due to the total number of $B_s^0 \bar{B}_s^0$ pairs. The significance of this result is 5.1 standard deviations, thus, our measurement constitutes the first observation of this decay. This measured branching fraction is in good agreement with the SM predictions [23], and it implies that the Belle II experiment [22] will reconstruct over 1000 of these decays. Such a sample would allow for a much higher sensitivity search for new physics in this $b \to s$ penguin-dominated decay.

**PROSPECTS OF CHARMLESS HADRONIC $B$ DECAYS AT BELLE II [22]**

The large datasets collected by Belle, BaBar, and LHCb have enabled the study of many charmless hadronic $B_{(s)}$ decays and have allowed for a detailed comparison with theoretical predictions and models. Some tantalizing questions have emerged and await the comparison with theoretical predictions and models.

The analogous isospin sum rules for the $\rho K (s)$ and $\rho K (s)$ decays are also promising avenues to resolve this puzzle, but are statistically limited and must be measured with high precision to reveal whether an anomalous pattern of direct $CP$ violation is emerging. The study of $B \to VV$ decays is still in its infancy due to the large statistics required to perform full angular analyses. While the majority of analyses at Belle and BaBar were limited to only measuring the longitudinal polarisation fraction, full angular analyses will be possible for many $VV$ channels at Belle II. Of particular interest are $pK^*$ decays, where a polarisation analysis will reveal if there is an enhanced contribution proportional to electromagnetic penguins. Belle II will also be uniquely suited to search for $CP$ asymmetries in $B \to 3h$ decays with multiple neutral particles in the final state, which will serve to complement related searches at LHCb, where the observation of large local $CP$ asymmetries in multiple channels has generated enormous interest from the theoretical and phenomenological communities. A size-able $B_s^0$ dataset will also be necessary to study rare decays such as the penguin dominated $B_s^0 \phi s^0$, where an excess above the SM prediction would be a clear indication of NP, and, e.g., the recently observed $B_s^0 \to K^0 \bar{K}^0$ decay, where Belle II expects to reconstruct $O(1000)$ events with $5 \text{ ab}^{-1}$ which will enable a $CP$ violation study and will serve to clarify the presence of NP in the decay. There are countless additional charmless hadronic $B_{(s)}$ decays which will be within the reach of Belle II. This will open up a new era of discovery and complementarity with other experiments.
