8 Received Day Month Year  
 9 Revised Day Month Year

10 We present recent results on charm physics at the Belle and Belle II experiments, cover-  
 11 ing measurements of charm lifetimes, branching fractions of the decays of charmed  
 12 mesons and baryons and the decay asymmetry parameters of two-body decays of charmed  
 13 baryons, searches for rare and forbidden decays, and measurements of  $CP$  violating pa-  
 14 rameters in the four-body decays of charmed mesons and two-body decays of charmed  
 15 baryons.

16 *Keywords:* Charm physics;  $CP$  violation; Belle; Belle II.

17 PACS numbers:

#### 18 1. Charm production at Belle and Belle II

19 The Belle II experiment, operating in the energy-asymmetric  $e^+e^-$  collider Su-  
 20 perKEKB, has been designed to conduct precise measurements of weak interaction  
 21 parameters, explore exotic hadrons, and probe for novel phenomena beyond the  
 22 Standard Model of particle physics. From 2019 to 2022, it accumulated an inte-  
 23 grated luminosity  $427 \text{ fb}^{-1}$ , thereby, a total  $1.4 \text{ ab}^{-1}$  from Belle and Belle II exper-  
 24 iments provides large samples of beauty and charm hadrons, as well as tau leptons.  
 25 There exist two primary avenues of charm production at Belle and Belle II, : (1)  
 26 via the continuum process  $e^+e^- \rightarrow c\bar{c}$ , having a cross section of  $\sigma = 1.3 \text{ nb}$ ; (2)  
 27 from decays of  $B$  mesons, where charmed hadrons are involved in the final state.  
 28 In Tab. 1, a comparison of available charm samples at BESIII, Belle, Belle II, and  
 29 LHCb, along with their own typical characters, is presented. Importantly, these  
 30 experiments will continue to collect data with increased luminosity in the future,  
 31 heralding a promising outlook for further research in charm physics.

\*presented at the 2024 International Workshop on Future Tau Charm Facilities (FCTF 2024).

## 2. Charm lifetime measurements

Hadron lifetimes are difficult to calculate theoretically, as they depend on nonperturbative effects arising from quantum chromodynamics (QCD). Comparing calculated and measured values improves our understanding of QCD. At Belle II, the decay-time resolution is about twice better than that at Belle and BABAR. Utilizing the early Belle II dataset, three world-leading charm lifetimes have been measured:  $\tau(D^0) = 410.5 \pm 1.1 \pm 0.8\text{ fs}$ ,  $\tau(D^+) = 1030.4 \pm 4.7 \pm 3.1\text{ fs}$ , and  $\tau(\Lambda_c^+) = 203.20 \pm 0.89 \pm 0.77\text{ fs}$ ;<sup>1,2</sup> and also a measurement<sup>3</sup> of  $\tau(\Omega_c^0) = 410.5 \pm 1.1 \pm 0.8\text{ fs}$  agrees with the measurement by LHCb<sup>4</sup> and confirm that the  $\Omega_c^0$  is not the shortest-lived weakly decaying charmed baryon.

Based on a clean sample of 116k  $D_s^+ \rightarrow \phi\pi^+$  reconstructed in 207  $\text{fb}^{-1}$  of data at Belle II, the  $D_s^+$  lifetime is extracted via an unbinned maximum likelihood fit to the lifetime ( $t$ ) and its uncertainty ( $\sigma_t$ ).<sup>5</sup> The likelihood function for  $i$ th event is calculated by:

$$\mathcal{L}(\tau|t^i, \sigma_t^i) = f_{\text{sig}} P_{\text{sig}}(t^i|\tau, \sigma_t^i) P_{\text{sig}}(\sigma_t^i) + (1 - f_{\text{sig}}) P_{\text{bkg}}(t^i|\tau, \sigma_t^i) P_{\text{bkg}}(\sigma_t^i)$$

where  $P_{\text{sig}}(\sigma_t^i)$  and  $P_{\text{bkg}}(\sigma_t^i)$  exist to avoid the Punzi bias. The fitted results are shown in Figure 1, and we obtain  $\tau_{D_s^+} = (499.5 \pm 1.7 \pm 0.9)\text{ fs}$ , the world most precise measurement to date. Thus, Belle II has made the world's most precise measurements of the  $D^{0,+}$ ,  $D_s^+$ ,  $\Lambda_c^+$  lifetimes; their small systematic uncertainty demonstrates the excellent performance and understanding of the Belle II detector.

Figure 1. Invariant mass of reconstructed  $D_s^+ \rightarrow \phi\pi^+$  candidates; the projections of lifetime extraction with a fitting on  $(t, \sigma_t)$ .<sup>5</sup>

### 51 3. Measurement of branching fraction and decay asymmetry 52 parameter

#### 53 3.1. Branching fraction of Cabibbo-suppressed decays of charmed 54 mesons

55 Cabibbo-suppressed (CS) hadronic decays of charm mesons offer a potent avenue  
56 for exploring new physics. Precise measurements of their branching fractions are  
57 of paramount importance. Singly Cabibbo-suppressed (SCS) charm decays serve as  
58 essential probes to search for charm  $CP$  violation (CPV) and probe physics beyond  
59 the SM. The abundant charm sample available from Belle and Belle II provides  
60 an excellent opportunity to accurately measure their branching fractions. Recently,  
61 Belle reported several first or most precise branching fractions of charmed meson  
62 decays, based on the full dataset. The invariant mass distributions of reconstructed  
63 decays are shown in Figure 2. Using the corresponding well-measured reference  
64 modes, we obtain branching fractions ( $\mathcal{B}$ ) of three SCS decays:<sup>6,7</sup>

$$\mathcal{B}(D^+ \rightarrow K^+ K^- \pi^+ \pi^0) = (7.08 \pm 0.08 \pm 0.16 \pm 0.20) \times 10^{-3}, \quad (1)$$

$$\mathcal{B}(D_s^+ \rightarrow K^+ \pi^- \pi^+ \pi^0) = (9.44 \pm 0.34 \pm 0.28 \pm 0.32) \times 10^{-3}, \quad (2)$$

$$\mathcal{B}(D_s^+ \rightarrow K^+ K^- K_S^0 \pi^+) = (1.29 \pm 0.14 \pm 0.04 \pm 0.11) \times 10^{-4}; \quad (3)$$

65 and one DCS decays:<sup>6</sup>

$$\mathcal{B}(D^+ \rightarrow K^+ \pi^- \pi^+ \pi^0) = (1.05 \pm 0.07 \pm 0.02 \pm 0.03) \times 10^{-3}, \quad (4)$$

66 where the last one confirms the BESIII finding<sup>8,9</sup> of a significantly larger  $\mathcal{B}$  than  
67 other known DCS decays.

#### 68 3.1.1. Branching fraction of charmed baryon decays

69 The weak decays of charmed baryons provide an excellent platform for understand-  
70 ing QCD with transitions involving the charm quark. The decay amplitudes consist  
71 of factorizable and non-factorizable contributions. Experimentally, the study of  
72 charmed baryons is more challenging than that of charmed meson due to smaller ex-  
73 perimental samples. Some CF decays are still poorly or not yet measured. Recently,  
74 Belle and Belle II reported many branching fractions of charmed baryons.<sup>10–12,14</sup>

## 4 Longke Li

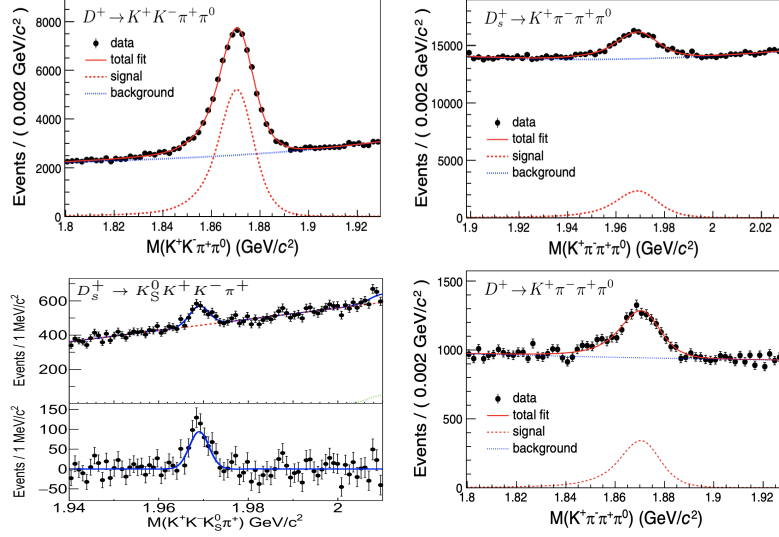

Figure 2. Invariant mass of reconstructed  $D$  candidates for the SCS decays  $D^+ \rightarrow K^+ K^- \pi^+ \pi^0$ ,  $D_s^+ \rightarrow K^+ \pi^- \pi^+ \pi^0$ ,  $D_s^+ \rightarrow K^+ K^- K_S^0 \pi^+$ , and the DCS decay  $D^+ \rightarrow K^+ \pi^- \pi^+ \pi^0$ .

- 75 The distributions of invariant mass of reconstructed  $\Lambda_c^+$  in six decay channels, and their corresponding fit results, are shown in Figure 3.

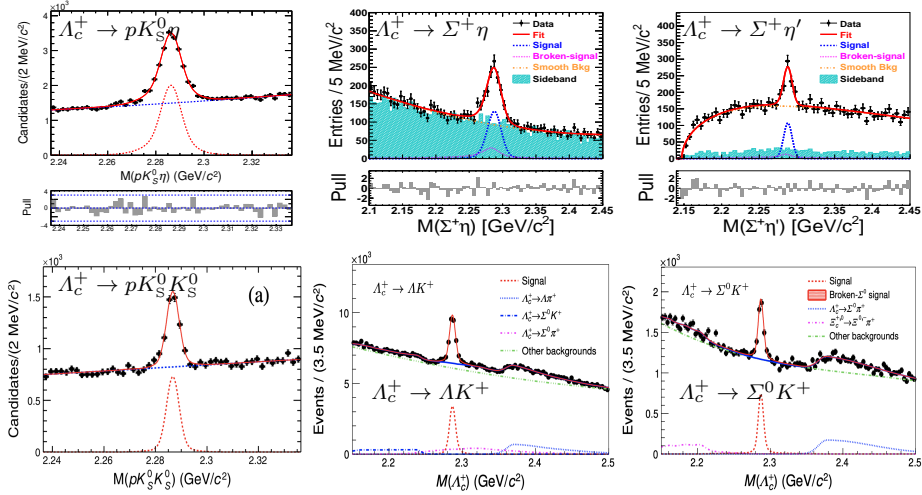

Figure 3. Invariant mass distributions of reconstructed  $\Lambda_c^+$  candidates and their corresponding fit results for six decay modes.

77 We report the branching fractions of three CF and three SCS decays:

$$\mathcal{B}(\Lambda_c^+ \rightarrow pK_s^0\eta) = (4.35 \pm 0.10 \pm 0.20 \pm 0.22) \times 10^{-3}, \quad (5)$$

$$\mathcal{B}(\Lambda_c^+ \rightarrow \Sigma^+\eta) = (3.14 \pm 0.35 \pm 0.17 \pm 0.25) \times 10^{-3}, \quad (6)$$

$$\mathcal{B}(\Lambda_c^+ \rightarrow \Sigma^+\eta') = (4.16 \pm 0.75 \pm 0.25 \pm 0.33) \times 10^{-3}, \quad (7)$$

$$\mathcal{B}(\Lambda_c^+ \rightarrow pK_s^0K_s^0) = (2.35 \pm 0.12 \pm 0.07 \pm 0.12) \times 10^{-4}, \quad (8)$$

$$\mathcal{B}(\Lambda_c^+ \rightarrow \Lambda K^+) = (6.57 \pm 0.17 \pm 0.11 \pm 0.35) \times 10^{-4}, \quad (9)$$

$$\mathcal{B}(\Lambda_c^+ \rightarrow \Lambda K^+) = (3.58 \pm 0.19 \pm 0.06 \pm 0.19) \times 10^{-4}, \quad (10)$$

78 and five results for the  $\Xi_c^0$  and  $\Omega_c^0$  decays:

$$\mathcal{B}(\Xi_c^0 \rightarrow \Xi^0\pi^0) = (6.9 \pm 0.3 \pm 0.5 \pm 1.5) \times 10^{-3}, \quad (11)$$

$$\mathcal{B}(\Xi_c^0 \rightarrow \Xi^0\eta) = (1.6 \pm 0.2 \pm 0.2 \pm 0.4) \times 10^{-3}, \quad (12)$$

$$\mathcal{B}(\Xi_c^0 \rightarrow \Xi^0\eta') = (1.2 \pm 0.3 \pm 0.1 \pm 0.3) \times 10^{-3}, \quad (13)$$

$$\frac{\mathcal{B}(\Omega_c^0 \rightarrow \Xi^-\pi^+)}{\mathcal{B}(\Omega_c^0 \rightarrow \Omega^-\pi^+)} = 0.253 \pm 0.052 \pm 0.030, \quad (14)$$

$$\frac{\mathcal{B}(\Omega_c^0 \rightarrow \Xi^-K^+)}{\mathcal{B}(\Omega_c^0 \rightarrow \Omega^-\pi^+)} < 0.070. \quad (15)$$

79 All of these results are the first or most precise measurements to date.

### 80 3.1.2. Decay asymmetry parameters of two-body decays of charmed baryons

81 The decay asymmetry parameter  $\alpha$  was introduced by Lee and Yang to study  
 82 the parity-violating and parity-conserving amplitudes in weak hyperon decays. In  
 83  $1/2^+ \rightarrow 1/2^+ + 0^-$ ,  $\alpha \equiv 2 \cdot \text{Re}(S^*P)/(|S|^2 + |P|^2)$ , where  $S$  and  $P$  denote the parity-  
 84 violating  $S$ -wave and parity-conserving  $P$ -wave amplitudes, respectively. Taking  
 85  $\Lambda_c^+ \rightarrow \Lambda h^+$ ,  $\Sigma^+ h^0$  decays for example, the differential decay rate has a dependence  
 86 on  $\alpha$ :

$$\frac{dN(\Lambda_c^+ \rightarrow \Lambda h^+)}{d \cos \theta_\Lambda} \propto 1 + \alpha_{\Lambda_c^+} \alpha_- \cos \theta_\Lambda, \quad (16)$$

87 where  $\alpha_-$  is hyperon decay asymmetry parameter. For  $\Lambda_c^+ \rightarrow \Sigma^0 h^+$  decays, consid-  
 88 ering  $\alpha(\Sigma^0 \rightarrow \gamma \Lambda)$  is zero due to parity conservation for an electromagnetic decay,  
 89 the differential decay rate is

$$\frac{dN(\Lambda_c^+ \rightarrow \Sigma^0 h^+)}{d \cos \theta_{\Sigma^0} d \cos \theta_\Lambda} \propto 1 - \alpha_{\Lambda_c^+} \alpha_- \cos \theta_{\Sigma^0} \cos \theta_\Lambda \quad (17)$$

90 By studying the hyperon helicity angle, we can extract  $\alpha$  from charmed baryon  
 91 decays. The results are listed in Tab. 2.

## 92 4. Search for rare or forbidden decays in charm sector

93 In the Standard Model (SM), the weak-current interaction has an identical coupling  
 94 to all lepton generations (Lepton Flavor Universality (LFU)). LFU can be tested

6 Longke Li

95 in semi-leptonic decays, such as  $\Xi_c^0 \rightarrow \Xi^0 \ell^+ \ell^-$  where a comparison of  $\ell = e$  and  $\mu$   
 96 decay rates would comprise such a test. Recently Belle reported a search for  $\Xi_c^0 \rightarrow$   
 97  $\Xi^0 \ell^+ \ell^-$  based on the Belle full data set.<sup>21</sup> The fits of invariant mass of reconstructed  
 98  $\Xi_c^0$  candidates for signal modes and reference mode are shown in Figure 4. The upper  
 99 limits on branching fractions relative to reference mode  $\Xi_c^0 \rightarrow \Xi^- \pi^+$  are measured  
 100 to be  $\frac{\mathcal{B}(\Xi_c^0 \rightarrow \Xi^- e^+ e^-)}{\mathcal{B}(\Xi_c^0 \rightarrow \Xi^- \pi^+)} < 6.7 \times 10^{-3}$  and  $\frac{\mathcal{B}(\Xi_c^0 \rightarrow \Xi^- \mu^+ \mu^-)}{\mathcal{B}(\Xi_c^0 \rightarrow \Xi^- \pi^+)} < 4.3 \times 10^{-3}$ . A more precise  
 101 analysis based on larger data samples collected by Belle II is expected in the future.

 Figure 4. The invariant mass of reconstructed  $\Xi_c^0$  candidates for signal modes  $\Xi_c^0 \rightarrow \Xi^0 \ell^+ \ell^-$  and reference mode  $\Xi_c^0 \rightarrow \Xi^- \pi^+$ .

102

103

104

105

106

Baryon number violation (BNV) is one of the crucial conditions to create matter-  
 antimatter asymmetry as observed in the universe. Several grand unified theories,  
 supersymmetry and other SM extensions propose BNV processes of nucleons. The  
 $D \rightarrow p\ell$  decays violate baryon (B) and lepton (L) numbers but their difference is

107 conserved ( $\Delta(B-L) = 0$ ). The previous stringent limit is  $\mathcal{B}(D^0 \rightarrow \bar{p}e^+) < 1.2 \times 10^{-6}$   
 108 at a 90% C.L. and recent BESIII result is  $\mathcal{B}(D^0 \rightarrow pe^-) < 2.2 \times 10^{-6}$ . Recently,  
 109 Belle reported a stricter upper limits:  $(5-8) \times 10^{-7}$  dependent on the decay modes,  
 as shown in Table 3.

Table 3. Reconstruction efficiency ( $\varepsilon$ ), signal yield ( $N_S$ ), signal significance ( $S$ ), upper limit on the signal yield ( $N_{p\ell}^{\text{UL}}$ ), and branching fraction ( $\mathcal{B}$ ) at 90% confidence level for baryon number violating decay modes.

Decay mode	$\varepsilon(\%)$	$N_S$	$S(\sigma)$	$N_{p\ell}^{\text{UL}}$	$\mathcal{B} (10^{-7})$
$D^0 \rightarrow pe^-$	10.2	$-6.4 \pm 8.5$	–	17.5	$< 5.5$
$\bar{D}^0 \rightarrow pe^-$	10.2	$-18.4 \pm 23.0$	–	22.0	$< 6.9$
$D^0 \rightarrow \bar{p}e^+$	9.7	$-4.7 \pm 23.0$	–	22.0	$< 7.2$
$\bar{D}^0 \rightarrow \bar{p}e^+$	9.6	$7.1 \pm 9.0$	0.6	23.0	$< 7.6$
$D^0 \rightarrow p\mu^-$	10.7	$11.0 \pm 23.0$	0.9	17.1	$< 5.1$
$\bar{D}^0 \rightarrow p\mu^-$	10.7	$-10.8 \pm 27.0$	–	21.8	$< 6.5$
$D^0 \rightarrow \bar{p}\mu^+$	10.5	$-4.5 \pm 14.0$	–	21.1	$< 6.3$
$\bar{D}^0 \rightarrow \bar{p}\mu^+$	10.4	$16.7 \pm 8.8$	1.6	21.4	$< 6.5$

110

## 111 5. Charm $CP$ violation searches

112 The violation of  $CP$ -symmetry, the combination of charge conjugation symmetry  
 113 and parity asymmetry, is essential for elucidating the matter-antimatter asymmetry  
 114 in the universe. In the Standard Model (SM) of particle physics, the sole source of  
 115  $CP$  violation (CPV) arises from a single complex phase in the Cabibbo-Kobayashi-  
 116 Maskawa matrix. However, this source is insufficient to account for the observed  
 117 matter-antimatter asymmetry. Therefore, we need new CPV sources beyond the  
 118 SM. Charm CPV in the SM is very small, at level of  $\mathcal{O}(10^{-3})$  or smaller, but new  
 119 physics (NP) may enhance it. Therefore, a study of charm CPV may help to test  
 120 the SM and act as a sensitive probe for NP. Experimentally, we have only one CPV  
 121 observation in charm sector:  $\Delta A_{CP}(D^0 \rightarrow K^+K^-, \pi^+\pi^-) = (-15.4 \pm 2.9) \times 10^{-4}$   
 122 ( $5.3\sigma$ ) from LHCb. To understand such CPV, we need to work on more channels  
 123 and improve the precision of measured  $CP$  asymmetries. On the other hand, CPV  
 124 has been observed in the open-flavored meson sector, but not yet in the baryon  
 125 sector. Baryogenesis, the process by which the baryon-antibaryon asymmetry of  
 126 the universe developed, is directly related to baryon CPV. Discovering the CPV  
 127 in charmed baryon decays is correctly one of the main targets of charm physics.  
 128 Recently we have reported CPV searches in four-body decays of charmed mesons,  
 129 and  $\alpha$ -induced CPV and direct CPV in  $\Lambda_c^+$  two-body decays.

### 130 5.1. $CPV$ in four-body decays of charmed mesons

131 Sensitivity to CPV varies with the decay channel, motivating CPV searches in di-  
 132 verse charm decays. The  $D$  four-body decays, with large branching fractions and

8 Longke Li

133 involving various intermediate processes, provide a good platform for CPV searches.  
 134 CPV in  $D$  four-body decay was probed with triple-product asymmetries by the  
 135 FOCUS, BABAR, LHCb and Belle experiments. The triple-product (TP) is de-  
 136 fined in the  $D$  rest frame using the momenta of three particles in the final state,  
 137  $C_{\text{TP}} = \vec{p}_i \cdot (\vec{p}_j \times \vec{p}_k)$  for  $D \rightarrow P_i P_j P_k P_l$  decays, and satisfies  $CP(C_{\text{TP}}) = -\bar{C}_{\text{TP}}$ .  
 138 The sign of  $C_{\text{TP}}$  denotes whether the  $\vec{p}_i$  points “upward” or “downward” in the  
 139 plane defined by  $\vec{p}_j$  and  $\vec{p}_k$ , therefore, its asymmetry is called an up-down asymme-  
 140 try. The TP asymmetries in  $D^+$  and  $D^-$  decays are defined as

$$A_T(D^+) = \frac{N_+(C_T > 0) - N_+(C_T < 0)}{N_+(C_T > 0) + N_+(C_T < 0)}, \quad (18)$$

$$\bar{A}_T(D^-) = \frac{N_-(-\bar{C}_T > 0) - N_-(-\bar{C}_T < 0)}{N_-(-\bar{C}_T > 0) + N_-(-\bar{C}_T < 0)}. \quad (19)$$

141 And their difference is assigned as a  $CP$ -violating parameter, i.e.  $a_{CP}^{\text{T-odd}} =$   
 142  $\frac{1}{2} \cdot (A_T(D^+) - \bar{A}_T(D^-))$ . This parameter  $a_{CP}^{\text{T-odd}} \propto \sin \phi \cos \delta$ , where  $\phi$  and  $\delta$  are  
 143 the weak and strong phase differences, respectively, between at least two ampli-  
 144 tudes contributing to the decay. The  $a_{CP}^{\text{T-odd}}$  has its largest value when  $\delta = 0$ , while  
 145 a non-zero direct  $CP$  asymmetry requires  $\delta \neq 0$ , therefore  $a_{CP}^{\text{T-odd}}$  is an observable  
 146 complementary to direct  $CP$  asymmetry.

147 Recently Belle searched for CPV with TP asymmetries in the decays of  $D^0 \rightarrow$   
 148  $K_S^0 K_S^0 \pi^+ \pi^-$ ,<sup>22</sup>  $D_{(s)}^+ \rightarrow K_S^0 h^+ \pi^+ \pi^-$ ,<sup>7</sup> and  $D_{(s)}^+ \rightarrow K h \pi^+ \pi^0$ .<sup>23</sup> They are listed in  
 149 Figure 5. Most of these  $a_{CP}^{\text{T-odd}}$  results from Belle are first or most precise measure-  
 150 ments.

## 151 5.2. CPV in $\Lambda_c^+ \rightarrow \Lambda K^+, \Sigma^0 K^+$

152 Recently, a search for direct CPV and  $\alpha$ -induced CPV in  $\Lambda_c^+ \rightarrow \Lambda K^+, \Sigma^0 K^+$  was  
 153 reported based on the Belle full data set.<sup>11</sup>

154 For SCS decay, for example  $\Lambda_c^+ \rightarrow \Lambda K^+$ , the raw asymmetry includes several  
 155 sources:

$$A_{\text{raw}} = A_{CP}^{\Lambda_c^+ \rightarrow \Lambda K^+} + A_{CP}^{\Lambda \rightarrow p \pi^-} + A_\varepsilon^\Lambda + A_\varepsilon^{K^+} + A_{\text{FB}}^{\Lambda_c^+} \quad (20)$$

156 where  $A_{CP}^{\Lambda_c^+ \rightarrow \Lambda K^+}$  ( $A_{CP}^{\Lambda \rightarrow p \pi^-}$ ) is the  $CP$  asymmetry associated with  $\Lambda_c^+$  ( $\Lambda$ ) decay;  
 157  $A_\varepsilon^\Lambda$  is an asymmetry arising from detection efficiencies of  $\Lambda$  and  $\bar{\Lambda}$ ;  $A_\varepsilon^{K^+}$  is the  
 158  $K^+$  reconstruction and identification asymmetry and can be removed by weighting  
 159  $w_{\Lambda_c^+, \bar{\Lambda}_c^-} = 1 \mp A_\varepsilon^{K^+} [\cos \theta, p_T]$ ;  $A_{\text{FB}}^{\Lambda_c^+}$  arises from the forward-backward asymmetry of  
 160  $\Lambda_c^+$  production due to  $\gamma$ - $Z^0$  interference and higher-order QED effects in  $e^+ e^- \rightarrow c \bar{c}$   
 161 collisions. We use the corresponding CF modes,  $\Lambda_c^+ \rightarrow \Lambda \pi^+$  and  $\Lambda_c^+ \rightarrow \Sigma^0 \pi^+$ , as  
 162 reference modes to remove the common asymmetry sources:  $A_{CP}^{\Lambda \rightarrow p \pi^-}$ ,  $A_\varepsilon^\Lambda$  and  $A_{\text{FB}}^{\Lambda_c^+}$ .  
 163 Under the current precision, the CPV in charm CF mode is consistent with zero,  
 164 i.e.  $A_{CP}^{\Lambda_c^+ \rightarrow \Lambda \pi^+} = 0$ . Finally, we have first results of a search for direct  $CP$  asymmetry

Figure 5. Belle results for  $a_{CP}^{T-odd}$  along with other measurements for  $D^0$  and  $D_{(s)}^+$  decays. For decays in which more than one measurement has been made, the world average value is plotted.

165 in two-body SCS decays of charmed baryons:

$$A_{CP}^{\text{dir}}(\Lambda_c^+ \rightarrow \Lambda K^+) = (+2.1 \pm 2.6 \pm 0.1)\%, \quad (21)$$

$$A_{CP}^{\text{dir}}(\Lambda_c^+ \rightarrow \Sigma^0 K^+) = (+2.5 \pm 5.4 \pm 0.4)\%. \quad (22)$$

166 For  $\Lambda_c^+ \rightarrow \Lambda h^+$  decays, the differential decay rate depends on  $\alpha$  parameters and  
167 one helicity angle:

$$\frac{dN}{d \cos \theta_\Lambda} \propto 1 + \alpha_{\Lambda_c^+} \alpha_- \cos \theta_\Lambda, \quad (23)$$

168 where  $\alpha_{\Lambda_c^+}$  is the decay asymmetry parameter of  $\Lambda_c^+ \rightarrow \Lambda h^+$ , and  $\theta_\Lambda$  is the angle  
169 between the proton momentum and the direction opposite the  $\Lambda_c^+$  momentum in  
170 the  $\Lambda$  rest frame.

171 For  $\Lambda_c^+ \rightarrow \Sigma^0 h^+$  decays, considering  $\alpha(\Sigma^0 \rightarrow \gamma \Lambda)$  is zero due to parity conser-  
172 vation for an electromagnetic decay, the differential decay rate is given by

$$\frac{dN}{d \cos \theta_{\Sigma^0} d \cos \theta_\Lambda} \propto 1 - \alpha_{\Lambda_c^+} \alpha_- \cos \theta_{\Sigma^0} \cos \theta_\Lambda, \quad (24)$$

173 where  $\theta_\Lambda$  ( $\theta_{\Sigma^0}$ ) is the angle between the proton ( $\Lambda$ ) momentum and the direction  
174 opposite the  $\Sigma^0$  ( $\Lambda_c^+$ ) momentum in the  $\Lambda$  ( $\Sigma^0$ ) rest frame. Since  $\alpha$  is a CP-odd

10 Longke Li

175 observable, the corresponding  $CP$ -violating parameter is defined as

$$A_{CP}^{\alpha} = \frac{\alpha_{\Lambda_c^+} + \alpha_{\bar{\Lambda}_c^-}}{\alpha_{\Lambda_c^+} - \alpha_{\bar{\Lambda}_c^-}}. \quad (25)$$

176 Under  $CP$  conservation, we have  $\alpha_{\Lambda_c^+} = -\alpha_{\bar{\Lambda}_c^-}$ . We measured the  $\alpha$ -parameters  
 177 for the separate  $\Lambda_c^+$  and  $\bar{\Lambda}_c^-$  samples, as shown in Figure 6 for  $\Lambda_c^+ \rightarrow \Lambda K^+$ , and  
 178 calculate the  $\alpha$ -induced CPV parameter  $A_{CP}^{\alpha}$ . We have

$$A_{CP}^{\alpha}(\Lambda_c^+ \rightarrow \Lambda K^+) = -0.023 \pm 0.086 \pm 0.071, \quad (26)$$

$$A_{CP}^{\alpha}(\Lambda_c^+ \rightarrow \Sigma^0 K^+) = +0.08 \pm 0.35 \pm 0.14. \quad (27)$$

179 No evidence of CPV is found in these two decays.

180 We also probe the  $\Lambda$ -hyperon CPV in CF decays  $\Lambda_c^+ \rightarrow \Lambda \pi^+$  and  $\Lambda_c^+ \rightarrow \Sigma^0 \pi^+$ ,  
 181 inspired by a theoretical paper.<sup>24</sup> The  $\Lambda$ -hyperon  $CP$  asymmetry  $A_{CP}^{\alpha}(\Lambda \rightarrow p \pi^-)$   
 182 can be extracted from the total  $\alpha$ -induced  $CP$  asymmetry of  $\Lambda_c^+$  decay chain:

$$A_{CP}^{\alpha}(\text{total}) \equiv \frac{\alpha_{\Lambda_c^+} \alpha_- - \alpha_{\bar{\Lambda}_c^-} \alpha_+}{\alpha_{\Lambda_c^+} \alpha_- + \alpha_{\bar{\Lambda}_c^-} \alpha_+} = A_{CP}^{\alpha}(\Lambda \rightarrow p \pi^-). \quad (28)$$

183 for Cabibbo-favored (CF) decays  $\Lambda_c^+ \rightarrow (\Lambda, \Sigma^0) \pi^+$ ,  $\alpha_{\Lambda_c^+} = -\alpha_{\bar{\Lambda}_c^-}$  since no  $CP$   
 184 asymmetry is expected in the SM. CPV in hyperon decays is predicted to be at the  
 185 level of  $\mathcal{O}(10^{-4})$  or smaller in the SM<sup>25-28</sup> and can be enhanced to reach the level  
 186 of  $10^{-3}$  in some new physics models.<sup>28-32</sup> The average value of  $A_{CP}^{\alpha}(\Lambda \rightarrow p \pi^-)$  in  
 187 two such CF modes is calculated to be

$$A_{CP}^{\alpha}(\Lambda \rightarrow p \pi^-) = +0.013 \pm 0.007 \pm 0.011. \quad (29)$$

188 This is the first measurement of hyperon CPV searches in CF charm decays. No  
 189 evidence of  $\Lambda$ -hyperon CPV is found.

Figure 6. The  $\cos \theta_{\Lambda}$  distribution of  $\Lambda_c^+ \rightarrow \Lambda K^+$  at Belle after efficiency-correction. We fit with a linear function of  $1 + \alpha_{\Lambda_c^{\pm}} \alpha_{\mp} \cos \theta_{\Lambda}$  with goodness-of-fit  $\chi^2/9 = 1.04, 0.57$ , respectively.

## 190 6. Summary

191 Belle continues to produce the fruitful charm results, even though its data taking  
 192 finished 13 years ago. Belle II has joined the game since 2019. Now a dataset with  
 193  $427 \text{ fb}^{-1}$  is available. We reported some recent results on measurements of  $\mathcal{B}$  and  
 194  $\alpha$ , CPV searches in the charmed meson and baryon decays, and several searches  
 195 for rare or forbidden decays. By utilizing the early dataset at Belle II, we obtain  
 196 the world's best  $\tau(D^{0,+})$ ,  $\tau(D_s^+)$ , and  $\tau(A_c^+)$ , and confirmation of the LHCb  $\tau(\Omega_c^0)$   
 197 result. More charm results based on a combined dataset of  $1.4 \text{ ab}^{-1}$  at Belle and  
 198 Belle II will be forthcoming. The scheduled luminosity accumulation, as shown in  
 Figure 7, promise the fruitful charm results at Belle II in the future.
